(54) Title: MODIFIED BIOLOGICAL MATERIAL

#### (57) Abstract

(30) Priority data:

Conventionally, animal tissue from one species can only be transplanted into another species when the species are concordant; otherwise, hyperimmune rejection ensues. In this invention, donor tissue is modified, for example by being transgenic, to express or otherwise be in association with one or more substances, referred to as homologous complement restriction factors (HCRFs), which are active in the recipient species to prevent the complete activation of complement and therefore rejection. The invention is in part based on the discovery that the alternative pathway of complement activation, rather than the classical pathway, is responsible for hyperacute discordant xenograft rejection.

#### MODIFIED BIOLOGICAL MATERIAL

2

This invention relates to biologically compatible material for use in transplants, and to the production and use of such material.

6

7 The replacement of failed or faulty animal (particularly human) tissue, including organs, has over 8 9 the last four decades become a common place therapy in 10 clinical medicine. These replacement therapies range 11 for example from the use of the polyethylene terephthalate sold under the trade mark DACRON by 12 13 DuPont to repair faulty blood vessels to the use of saphenous vein as an autograft to by-pass blocked 14 arteries and to the transplantation from one human to 15 16 another of a heart.

17

18 Organ transplantation has undergone significant 19 development with modern immunosuppressants allowing 20 high success rates to be achieved at relatively modest 21 The demand for organ transplantation has 22 increased rapidly. There are now more than 20,000 23 organ transplants per annum carried out worldwide. 24 This, however, represents only approximately 15% of the 25 need as assessed by current criteria. 26 supply/demand ratio of donor organs of all types can not be met from existing sources. This is perhaps best 27 28 illustrated with the demand for heart transplantation. The first heart transplantation by Barnard in 1967 29 30 generated considerable press coverage. Within a year, 31 101 heart transplants had been performed in 22 32 countries by 64 different surgical teams. 33 sillusionment followed the poor results obtained so

that by the early 1970s fewer than 30 transplants per 1 year were being performed worldwide. 2 The introduction 3 of cyclosporin immuno-suppression, however, revolutionarised heart transplantation so that most centres can now anticipate success rates for heart 5 transplantation of more than 80% one year graft (and 6 patient survival). As expertise is gained, 7 survival rate can reasonably be expected to increase 8 The success of this procedure, of course, 9 further. fuels demand so that the medical profession and the 10 general public become more aware that heart 11 12 transplantation offers a real alternative to death, so more and more patients are referred for the procedure. 13 Currently, over 2,000 heart transplants per annum are 14 performed. 15

16

17 Today, the greatest risk of death in heart 18 transplantation is while waiting for a suitable donor 19 organ to become available. While the artificial heart 20 offers a short-term support device for these patients, 21 long-term demands are for more heart transplant centres 22 and a greater donor supply. The potential number of 23 individuals who might benefit from cardiac 24 transplantation has never been scientifically 25 established, but published estimates of the need for 26 heart transplantation have ranged widely between 50 and 27 250 people per million per year depending on selection 28 criteria, age of recipient, disease and so forth. 29 Whatever the actual figure may be, it is quite clear already that current donor supply options are incapable 30 31 of meeting demand. Similar comments can be made for 32 kidney and liver transplantation, and it seems likely that once pancreas or Islet of Langerbans cell 33

- transplantation becomes a wid ly-accepted therap utic 1 2 procedure for the treatment of diabetes, shortage of
- 3 this tissue will also become a prime concern.

5 There are further disadvantages with current transplantation therapy. It is by no means always the 7 case that donor organs are fit for use in 8 transplantation, not least because many organ donors 9 are themselves victims of some accident (for example, a 10 road accident) which has caused death by injury to some 11 organ other than that which is being transplanted; 12 however, there may be some additional injury to or associated difficulty with the organ to be 13

14 15 transplanted.

Further, because of the unpredictable availability of 16 17 organs from donors, transplant surgery often can not be scheduled as a routine operation involving theatre time 18 19 booked some while in advance. All too frequently, 20 surgical teams and hospital administrators have to 21 react the moment a donor organ is identified and work unsocial hours, thereby adding to administrative and 22 23 personal difficulties.

24

In the case of heart, liver and lung transplants, if 25 rejection is encountered it will not usually be 26 27 possible to retransplant unless by chance another 28 suitable donor becomes available within a short space 29 of time.

30

31 Apart from the above medical difficulties, current 32 transplantation practice can in some cases involve social difficulties. In the first place, there may be 33

- 1 - - 1/4 - 1 - - 1/2/ - - - 1/4 - 1/4/4 - HUNNIN N - 1/4/4

4

religious objections to removing organs from potential 1 2 donors, particularly in cultures believing in 3 reincarnation. There are of course other ethical and 4 social difficulties encountered in removing organs from 5 dead humans, particularly as consent is required in 6 some countries. Finally, the appearance of a commercial trade in live kidney donors is causing concern, particularly in certain third world countries, and it would be socially desirable to suppress or 10 reduce such a trade.

ll

Conventional transplantation surgery, as outlined above 12 with its disadvantages, involves the transplantation 13 from one animal of a particular species (generally 14 15 human) to another of the same species. transplantations are termed allografts. Because of the 16 difficulties with conventional allograft supply, 17 18 outlined above, attention has focused on the possibility of using xenografts in transplantation. 19 20 Xenografting is the generic term commonly used for the 21 implantation of tissues, including cells and organs, 22 across species barriers.

23

24 There have already been several examples of the 25 successful use of xenografts in therapeutic replacement 26 schedules. For example, recent years have witnessed . 27 the use of pig tissue for aortic valve replacement, pig skin to cover patients with severe burns, and cow 28 29 umbilical vein as a replacement vein graft. All of 30 these xenografts have, however, one point in common: they provide a mechanical replacement only. The tissue 31 used is biologically non-functional. 32 The reason for this is that the immune processes existing in man 33

- immediately (within minutes or hours) destroy the cellular integrity of tissues from m st specis. Such
- 3 xenografts are known as discordant xenografts.

- The ferocity of this destruction is phylogenetically associated. Thus, tissue from the chimpanzee, which is a primate closely related to man, can survive in man in
- much the same way as an allograft; such a xenograft is
- 9 known as a concordant xenograft.

10

11 While it may be thought that concordant xenografts 12 might provide the answer to the difficulties with 13 allografts, in practice this is probably not the case. 14 Chimpanzees are much smaller than man and chimpanzee organs are generally not big enough to work in man. 15 the case of kidneys this may be overcome by 16 transplanting two chimpanzee kidneys to replace a 17 18 failed human kidneys, but for liver and heart this is clearly not a possibility. 19 Furthermore, chimpanzees breed slowly in nature and poorly in captivity, and the 20 Żl demand for chimpanzees as experimental animals 22 (particularly in the current era of research into Acquired Immune Deficiency Syndrome (AIDS)) means that, 23 24 yet again, demand is outstripping supply. 25 Additionally, there may be some social difficulty with

27 28

26

xenograft donors.

Attention has therefore refocused on discordant xenografts. It has been commonly believed that the reason why discordant xenografts fail so rapidly, is the existence in the recipient species of "naturally occurring" antibodies against as yet undefined antigens

the public acceptance of the use of other primates as

of the donor species (Shons et al (Europ. Surg. Res. 5 2 26-36 (1973)). The antibodies ar called "naturally 3 occurring" because they are found to exist in 4 individuals who have not had any immunological 5 challenge from the donor species.

6

The rapid rejection - known as hyperacute antibody-7 mediated rejection - of an organ graft is well 8 In the early 1960s, when (allograft) documented. 9 kidney transplantation became a routine treatment, it 10 was observed that transplanted kidneys were 11 occasionally rejected by the recipient whilst the 12 operation was still in progress. During a transplant 13 operation, the kidney will as a rule become red and 14 firm in consistency soon after the vessels of the 15 recipient and donor are sutured together. 16 17 transplants often produce urine almost immediately. the form of rejection where the graft is destroyed 18 while the patient is still on the table (hyperacute 19 rejection) the destructive processes begin in the first 20 few minutes or so after transplantation. When this 21 occurs, the kidney becomes bluish and patchy and then 22 The consistency of the organ is also 23 congested. altered. As a rule, the graft becomes oedematous, no 24 urine production occurs and the newly-transplanted 25 26 kidney is then immediately removed. It has become 27 clear that a humorally-mediated immunological response between preformed circulating antibodies in the 28 recipient and antigens in the donor kidney are 29 The only way to avoid its occurrence in 30 allografting is to check before transplantation that 31 32 there are no antibodies existing in the recipient 33 against the donor cells. With increased knowledge of

1 testing for such antibodi s (known as th cross match) 2 it has become clear that this generalisation that antibody in the recipient reacts against antigens in 3 4 the donor is not true and that hyperacute graft 5 destruction, when it involves transplants between 6 individuals of the same species is restricted to the existence of specific sorts of antibody known as T-warm 7 positive cross-match; and almost certainly these 8 9 antibodies belong to the IgG subclass. Furthermore. 10 the presence of these antibodies always results from a pre-existing immunisation procedure either as a result 11 of previous blood transfusions or as a result of 12 13 pregnancy or, most commonly, as a result of a failed 14 previous transplant.

15

The mechanism for hyperacute xenograft rejection has 16 17 largely been thought to be much the same as the mechanism for hyperacute allograft rejection, 18 19 outlined above. The literature on the mechanism of 20 xenograft rejection is extensive, stretching back some 83 years. During that time, only three publications 21 appear to have suggested a mechanism for xenograft 22 23 rejection which does not involve antibodies. 24 suggestion was that the alternative pathway of 25 complement activation was implicated in xenograft rejection (although not necessarily using such 26 27 terminology). The suggestion first appeared in 1976 in a paper by Schilling et al (Surgery, Gynaecology and 28 29 Obstetrics 142 29-32 (1976)). The suggestion was made again in 1988 and 1989 (the same data were published 30 31 twice) by Miyagawa et al (Transplantation 46(6) 825-830 (1988) and Transplantation Proceedings 21(1) 520-521 32 33 (1989)). However, the results were not conclusive,

because both these experiments suffered from substantially the same fault. The model chosen is 2 claimed by the authors to be a xenograft model in which 3 cross-species antibodies did not exist. However, it 4 now appears that the assays used to detect 5 cross-species antibodies were inadequate, and that the 6 inferences drawn in these papers were based on 7 8 inadequate data.

9

13

14

15

16

17

18

Most measures currently taken experimentally to avoid 10 or reduce rejection in xenografts involve ll. chemotherapeutically interfering with the recipient's 12 immune system, largely on a non-specific basis for example with cyclosporin A and immunosuppressants, by plasmaphoreses, by treatment with cobra venom factor, Staphylococcus protein A absorption of antibody and so on. This approach naturally follows from the chemotherapy that supports allografts.

19 20

This invention adopts a radically different approach: 21 instead of non-specifically interfering with the 22 recipient's immune system, the invention enables to co-23 administration of material which has the effect of the 24 donor graft being regarded as self by certain 25 components of the recipient's immune system. 26 particularly preferred embodiments, the donor tissue 27 itself is modified to appear immunologically to the 28 recipient to be self in certain respects. 29

30

31 It is has also been discovered that hyperacute xenograft rejection is not necessarily antibody-32 mediated. This arises from two observations. First, 33

in the absence of antibody but the presence of complement, hyperacut rejection is observed; secondly, in the presenc of antibody but the absence of complement, no hyperacute rejection is observed.

5

The invention is based on the discovery that complement 6 activation is pre-eminent in the hyperacute destruction 7 of a xenograft whether or not such activation is aided 8 9 by the binding of appropriate antibody molecules. Activation of the alternative pathway of complement can 10 be induced by a variety of cell products. 11 products are not restricted to foreign-invading cells 12 such as bacteria or xenografts but exist on many cells. 13 Thus, in principle, many cells of an individual could 14 activate the alternative pathway of complement, causing 15 massive auto-immune destruction. 16 That this does not happen is due to the existence of a number of 17 complement down-regulating proteins naturally present 18 in serum and on the surface of cells. 19 These molecules (referred to herein as "homologous complement 20 restriction factors") prevent the complete activation 21 of self complement either by the classical or 22 alternative pathway by the products of self cells, thus 23 preventing the auto-immune destruction of self. 24 functioning of such molecules is elegantly illustrated 25 in paroxysmal nocturnal haemoglobinuria. 26 disease, the membrane anchor of at least one of these 27 molecules (decay accelerating factor) is absent. 28 the protein is not retained in the erythrocyte cell 29 membrane and detaches from the cell, which activates 30 the alternative pathway of complement and is then lysed 31 thus causing haemoglobinuria. 32

33

According to a first aspect of the present inventi n, 1 2 there is provided a m thod of transplanting animal 3 tissue into a recipient, wherein the tissue is derived from a donor of a different species from the recipient, 4 5 the donor species being a discordant species with respect to the recipient, the method comprising 6 grafting the tissue into the recipient and providing in 7 8 association with the grafted tissue one or more 9 homologous complement restriction factors active in the recipient species to prevent the complete activation of 10

11 12 complement.

The word "tissue" as used in this specification means 13 any biological material that is capable of being 14 transplanted and includes organs (especially the 15 16 internal vital organs such the heart, lung, liver and kidney, pancreas and thyroid) cornea, 17 skin, blood 18 vessels and other connective tissue, cells including 19 blood and haematopoietic cells, Islets of Langerhans, 20 brain cells and cells from endocrine and other organs and body fluids (such as PPF), all of which may be 21 22 candidates for transplantation from one species to 23 another.

24

25 A "discordant species" is a species a (generally 26 vascularised) xenograft from which into the recipient 27 would normally give rise to a hyperacute rejection, 28 that is to say rejection within minutes or hours and 29 not days (Calne Transplant Proc 2:550, 1970). 30 hyperacute rejections will be well known to those 31 skilled in the art, and ay take place in under 24 32 hours, under 6 hours or even under one hour after 33 transplantation.

Complement and its activati n are now well known, and 1 are described in Roitt, <u>Bssential Immunology</u> (Fifth 1984) Blackwell Scientific Publications, Edition, The activity ascribed to complement (C') 4 depends upon the operation of nine protein components 5 (C1 to C9) acting in sequence, of which the first 6 consists of three major sub-fractions termed Clq, Clr Complement can be activated by the classical 8 or alternative pathway, both of which will now be 9 briefly described. IO

11

In the classical pathway, antibody binds to C1, whose 12 Cls subunit acquires esterase activity and brings about 1.3 the activation and transfer to sites on the membrane or 14 immune complex of first C4 and then C2. This complex 15 has "C3-convertase" activity and splits C3 in solution 16 to produce a small peptide fragment CJa and a residual 17 molecule C3b, which have quite distinct functions. C3a 18 has anaphylatoxin activity and plays no further part in 19 the complement amplification cascade. C3b is membrane 20 bound and can cause immune adherence of the 21 antigen-antibody-C3b complex, so facilitating 22 subsequent phagocytosis. 23

24

In the alternative pathway, the C3 convertase activity 25 is performed by C3bB, whose activation can be triggered 26 in particular microbial by extrinsic agents, 27 polysaccharides such as endotoxin, acting independently 28 of antibody. The convertase is formed by the action of 29 Factor D on a complex of C3b and Factor B. This forms 30 a positive feedback loop, in which the product of C3 31 breakdown (C3b) helps form more of the cleavage enzyme. 32

- In both the classical and alternative pathways, the C3b 1 level is maintain d by the action of a C3b inactivator 2
- (Factor I). C3b readily combines with Factor H to form 3
- a complex which is broken down by Factor I and loses 4
- its haemolytic and immune adherence properties. 5

- The classical and alternative pathways are common after 7 8 the C3 stage. C5 is split to give C5a and C5b
- fragments. C5a has anaphylatoxin activity and gives 9 10
- rise to chemotaxis of polymorphs. C5b binds as a complex with C6 and C7 to form a thermostable site on 11
- 12
- the membrane which recruits the final components C8 and 13
- C9 to generate the membrane attack complex (MAC).
- is an annular structure inserted into the membrane and projecting from it, which forms a transmembrane channel 15
- fully permeable to electrolytes and water. Due to the 16
- high internal colloid osmotic pressure, there is a net 17
- influx of sodium ions and water, leading to cell lysis. 18

19

- Homologous complement restriction factors (HCRFs) 20
- useful in the present invention can in general 21
- interfere with any part of the complement activation 22
- cascade. An HCRF may interfere solely with that part 23
- which constitutes the classical pathway, or solely with 24 25
- that part which constitutes the alternative pathway, or 26
- more usually may interfere with that part which is common to both the classical and alternative pathways. 27
- It is preferred that the HCRF regulator interfere with 28
- the common part of the pathway. 29
- The HCRF may be identical to a natural HCRF or simply have the 30
- 31 appropriate function. Synthetic and semi-synthetic
- HCRFs, including those prepared by recombinant DNA 32

technology and variants however prepared, are included within the term HCRF.

4 As has been mentioned above, homologous complement 5 restriction factors are substances which regulate the action of the complement cascade in such a way as to 7 reduce or prevent its lytic activity; they are used by 8 the animal body to label tissue as self to avoid 9 . autoimmune reaction. In this invention it is possible 10 in principle for the HCRF to be either membrane bound 11 or free in serum, although in practice it will be preferred to have the HCRF being membrane bound on 12 13 cells of the xenograft tissue. In this way, it is 14 easier for the HCRF to be "in association with" the graft tissue. Preferred HCRFs include putative cell 15 membr: 9 factors including the C3b/C4b receptor (CR1), 16 C3.dg \_eceptor (CR2), decay accelerating factor (DAF), C3b Inactivator and membrane cofactor protein (MCP). Putative serum HCRFs include Factor H, accelerating factor (DAF) and C4 binding protein These HCRFs all down-regulate the activity of complement by interference at the C3 stage. restriction factor (HRF), which blocks at C8, is also a

24 25 26

27

28

17 18

19 20

21

22

23

Many, but not all, of the genes for suitable HCRFs are located in the RCA (regulator of complement activation) locus, which map to band q32 of chromosome 1 (Rey-Campos et al J. Exp. Med. 167 664-669 (1988)).

putative membrane factor.

29 30

31 Although there has been some confusion with the 32 nomenclature and location of HCRFs, the factors C4BP, 33 CR1, DAF and Factor H are identified by Rey Campus et

1	al (loc. cit.) and in their earlier study (J. Exp. Med.
2	166 246-252 (1987)). Membrane cofactor protein (MCP)
3	is treated by some workers as synonymous with C4
4	binding protein (C4bp) and it may be that these two
5	factors are either related or identical. Rother and
6	Till ("The Complement System", Springer-Verlog, Berlin
7	(1988)) review the regulatory factors of C3 convertase
8	in section 1.2.3.2; they equate C4 binding protein
9	(C4bp) with decay accelerating factor and Factor H with
10	B <sub>1</sub> H-protein and C3b Inactivator Accelerator. No doubt
11	the nomenclature, localisation and characterisation of
12	HCRFs will continue to evolve, but it is to be
13	understood that the present invention contemplates the
14	use of all HCRFs as suitability and preference dictate.

18
19
         MAC-inhibiting protein (MIP) (Watts et al.
20
          (1988)).
21
     The C8bp/HRF/MIP protein is attached to the cell
22
     surface by means of a glycolipid anchor, as are CD59
23
     and DAF: these proteins are known to be functionally
24
     absent in paroxysmal nocturnal haemoglobinuria.
25
26
    An 18-20 kDa protein is also implicated at the MAC
27
28
    'level. The following are believed to be identical (but
    may not be):
29
30
31
         P-18 (Sugita et al (J. Biochem 104 633 (1988)));
32
         HRF-20 (Okada et al (Intl. Immunol 1 (1989)));
33
```

1 2 CO59 (Davies et al (J. Exp. Med. (Sept 1989))); 3 and . 4 Membrane inhibitor of reactive lysis (MIRL) 5 (Hologuin et al J. Clin. Invest 84 7 (1989))). 6 7 The evidence for the putative identity of these . 8 9 proteins is that the protein and/or cDNA sequences for CD59 and HRF-20 are shown to be identical: probably 10 they are the same as P-18/MIRL also. It should be 11 noted that there is some homology of the CD59/HRF.20 12 sequence with that of murine LY-6 antigen, which is 13 involved in T-cell activation (Gronx et al (I. Immuno). 14 142 3013 (1989))). 15 16 SP-40.40 is also involved in MAC regulation (Kivszbaum 17 18 et al EMBO 8, 711 (1989)). 19 It is preferred that the HCRF interfere with complement 20 activation at the C3 stage. MCP and DAF both block the 21 positive feedback loop in the alternative pathway of C3 activation, and these constitute preferred HCRFs. 23 24 The HCRF is provided in association with the grafted 25 26 tissue. This means that the HCRF is administered in such a way that the graft tissue is labelled as self, 27 but other foreign material, such as invading bacteria, 28 are not significantly so labelled. It may be possible 29 simply to administer parenterally, but locally to the 3.0 graft tissue, one or more appropriate HCRFs. 31 in practice this may not be preferred because of the 32 difficulty of causing adequate localisation of the HCRF 33

WO 91/05855 PCT/GB90/01575

18

at the graft tissue and because of the further difficulty that the HCRF may have to be repeatedly administered to the recipient after the graft has taken place; however, this could be overcome by the use of specialist pharmaceutical delivery systems.

6 7

8 9

10

11 12

13

14

15

16

17

18

19

It will generally be much more convenient to provide the HCRF in such a way that it is integrated with the cell membrane on donor tissue. Although there may be some benign infections of the transplanted tissue which by far the most could cause suitable expression, preferred route of achieving this end is for the donor tissue to be transgenic in that it contains and expresses nucleic acid coding for one or more HCRFs active in the recipient species when grafted into the recipient. Such transgenic tissue may continue to express an HCRF indefinitely. The HCRF may be genetically derived from the recipient species or less preferably from a closely related species for which concordant xenografts may be possible.

20 21 22

23

24

25

26

27

28

29

30

Although in principle the transgenic donor tissue may come from a cell culture, it is preferable for the donor tissue to come from a transgenic animal. The transgenic animal should express (or be capable of expressing) the HCRF in at least the tissue to be transplanted, for preference. However, even this is not essential, as it may be possible to bind the HCRF to the cell membranes of the donor tissue by some binding agent (such as a hybrid monoclonal antibody (Milstein & Cuello Nature 305 537 (1983)) or receptor.

31 32

- 1 The recipient species will primarily be human, but not
- 2 exclusively. Other primat s may be suitable
- 3 recipients, as may any other species where the
- 4 economics and ethics permit.

- 6 The donor species may be any suitable species which is
- 7 different from the recipient species and which, having
- 8 regard to the physiology of the recipient species is
- 9 able to provide appropriate tissue for transplantation.
- 10 For human recipients, it is envisaged that pig donors
- 11 will be suitable, but any other species may be
- 12 suitable.

13

- 14 According to a second aspect of the invention, there is
- 15 provided graftable animal cells or tissue of a donor
- 16 species, the cells or tissue being associated with one
- 17 or more homologous complement restriction factors
- 18 active in the intended recipient species to prevent the
- 19 complete activation of complement, the donor species
- 20 being a discordant species with respect to the
- 21 recipient species.

22

- 23 According to a third aspect of the invention there is
- 24 provided a transgenic animal having transplantable
- 25 tissue, which does not give rise to xenograft rejection
- on transplantation into or exposure to the immuno
- 27 system of at least one discordant species. A
- 28 discordant species is one which would normally
- 29 hyperacutely reject a xenograft from the animal.

30

- 31 The invention therefore encompasses the use of animal
- 32 tissue derived from a donor species and one or more
- 33 homologous complement restriction factors active in a

recipient species, wherein the donor species is a discordant species in relation to the recipient species, in the preparation of tissue graftable into the recipient species.

5

According to a fourth aspect of the invention, there is 6 provided a transgenic animal having cells capable of 7 expressing a homologous complement restriction factor 8 The homologous complement of another species. 9 restriction factor will generally be active in a 10 species which is discordant with respect to the species 11 The cells may be of one of the transgenic animal. 12 particular tissue, with preferences being as described 13 with reference to the first aspect of the invention, or 14 of more than one or all tissues, in Which case the 15 animal may become a donor of more than one tissue. 16 Such a transgenic animal may be regarded as a 17 collection of non-transformed (in the sense of 18 non-proliferative) cells. 19

20 21

22

23

24

According to a fifth aspect of the invention, there is provided a non-transformed animal cell capable of expressing one or more homologous complement restriction factors active in a species which is discordant with respect to the animal cell.

25 26

According to a sixth aspect of the invention, there is provided recombinant DNA comprising DNA coding for at least one homologous complement restriction factor and one or more sequences to enable the coding DNA to be expressed by a non-transformed animal cell. The animal cell may be a cell of a transgenic animal genetically incorporating the construct. As an alternative, the

cell may be a cultured organ or ther tissue such as an Isi t of Langerhans.

3

According to a seventh aspect of the invention, there 4 5 is provided a genetic construct suitable for б incorporation into the genetic material of an animal to 7 produce a transgenic animal, the construct comprising DNA coding for at least one homologous complement 8 9 restriction factor and one or more sequences to enable the coding DNA to be expressed in at least some cells 10 11 of a transgenic animal genetically incorporating the 12 construct. Such a genetic construct may be in the form 13 of a mini chromosome known as a YAC. As above, the 14 homologous complement restriction factor will generally 15 be active in a species which is discordant with respect

16 17

According to a eighth aspect of the present invention, there is provided a method of preparing a transgenic animal, the method comprising incorporating into an animal's genetic material DNA coding for at least one homologous complement restriction factor and one or more sequences to enable the coding DNA to be expressed in at least some cells of the transgenic animal.

to the species of the transgenic animal.

25

Methods of producing transgenic animals are in general becoming more widespread, and the detailed steps to be taken may be as now conventionally used in the art. For example, WO-A-8800239 discloses the steps needed in principle to construct a transgenic animal.

31

The actual method of incorporation of the construct into the cells of the transgenic animal may be by

micro-inj ction, by sperm-mediated incorporati n or any 1 2 other suitable method. The preliminary genetic manipulation may be carried out in a prokaryote, as is 3 generally preferred. 4 5 DNA coding for HCRFs is either available in cDNA form 6 or may be deduced using conventional cloning 7 The DNA coding for decay accelerating 8 techniques. factor (DAF) is probably the best characterised and has 9 been described by Medof et al (PNAS 84 2007-2011 10 A physical map of the RCA gene cluster is 11 (1987)). given in Rey-Campos et al (1988) (loc. cit.). Variants 12 13 of DAF and their preparation by recombinant DNA technology are disclosed in EP-A-0244267; such variants 14 may be used in the present invention. 15 16 17 Because of the better characterisation of the genetics 18 of DAF, and the known sequence of cDNA encoding DAF, DAF constitutes a preferred homologous complement 19 restriction factor. 20 21 Other preferred features of the second to seventh 22 23 aspects of the invention are as for the first aspect, 24 mutatis mutandis. 25 The invention will now be illustrated by the following 26 examples. In the examples, reference is made to the 27 . 28 drawings in which: 29 FIGURES 1A to 1E show successive ECG traces for a 30 31 rabbit's heart grafted onto neonate pigs in accordance with Example 1; 32

18	
19	EXAMPLE 1
20	
21	Xenograft Rejection Takes Place in the Absence of any
22	Antispecies Antibodies
23	
24	In general, animals cannot survive without circulating
25	immunoglobulins. These are produced by lymphocytes in
26	response to antigenic stimuli. In early neonatal life,
27	however, passively transferred maternal immunoglobulin
28	acts as a temporary substitute for this self-produced
29	antibody. This passively transferred immunoglobulin
30	confers protection on the young while early immune
31	experience is acquired. In mammals this passive
32	transfer of maternal immunoglobulin usually occurs both
33	transplacentally and via colorton In a few consistent

- however, the structure of the placenta is such that no maternal antibody can be transferred by this route. The pig is one such species. All maternal antibody is obtained from colostrum. Thus, new born pre-suckled
- 5 pigs are in principle immunoglobulin-free.

б

Targe white pigs were taken at birth and placed in a wooden cage warmed by hot-water bottles without being allowed to suckle. Two pigs from each farrowing were taken for each experiment. These animals weighed approximately lkg at the time of birth.

12

Baby New Zealand white rabbits weighing approximately 13 300gms were used as donors. These donors were 14 anaesthetised with hypnol and diazepam, the chest was 15 opened and a vena cava cannulated by means of a 19 16 gauge needle. Cold (+4°C) cardioplegia (Thomas No. 2) 17 was infused until the heart stopped beating and had 18 become perfused with cardioplegia. Cooling was also 19 applied externally with cold cardioplegia directly from 20 The rabbits heart was then removed using a syringe. 21 standard surgical techniques and stored in cardioplegia 22 solution at +4°C until required. It has been found 23 necessary to take these precautions because the rabbit フム heart proved to be highly susceptible to ischaemic 25 26 damage.

27

Recipient pigs were anaesthetised initially by Halothane/02 inhalation. An intravenous butterfly (23 gauge) needle was then inserted into a mammary vein, anaesthesia maintained by intravenous ketamine. The pig was simultaneously kept hydrated with intravenous

saline. Serum and EDTA bl d samples were drawn 2 pre-transplant. 3 The rabbit heart was grafted into the neck of the pigs 4 after the method of Heron (Acta Pathol. Microbiol. 5 <u>Scand</u>. **79** 366-372 (1971)). 6 The aorta was anastomised end to side (6-0 prolene) to the carotid artery and the 7 pulmonary artery anastomised to the jugular vein. 8 other cardiac vessels were ligated. 9 Hearts began beating within a few minutes of removal of clamps. 10 Heart rate was monitored throughout by a diascope/ECG 11 monitor. The pig neck was not closed during the 12 experiments, hearts were kept moist by covering with 13 14 cling film. 15 The ECG results are shown in Figures 1A to 1E. 16 17 trace shown in Figure 1A shows a normal heart beat immediately after transplantation. Pailure begins some 18 twenty minutes later (Figure 1B) and within an hour 19 (Pigure 1D) there is no detectable heart beat, 20 evidencing hyperacute rejection. 21 22 This example therefore demonstrates that hyperacute 23 rejection of discordant xenograft takes place even in 24 the absence of antibodies.

1	EXAMPLE 2
2	
3	The Neonatal Pigs used in Example 1 have no Antispecies
4	Antibody
5	
6	Rabbit anti-pig IgG was radiciodinated by the method of
7	Greenwood et al, Biochemical Journal 89 114-123 (1963)
8	modified by Davies and Howard (not published).
9	•
10	The following are added into a polystyrene tube (LP2
11	6 cm x 1 cm) in rapid succession:
12	
13	25-50µl protein (at 1mg/ml conc)
14	3-4µl Na <sup>125</sup> I (100 mCi/ml)
15	10µl chloramine-T (*4mg/5ml; 0.5M)
16	sodium phosphate buffer (pH 7.5)
17	* must be freshly prepared before use
18	
19	These components were allowed to mix for 30 seconds
20	with continuous agitation. Then the following were
21	quickly added:
22	
23	50µl DL-tyrosine (sat. sol. in 0.5ml sodium phosphate
24	buffer pH 7.5).
25	
26	300µl 2% BSA/PBS/azide
27	
28	The labelled protein is then separated from the
29	unreacted iodine, by the use of a small column
30	8cm x 1.0cm of Sephadex G-25 medium grade made up in
31	PBS/azide. The iodination reaction mixture is
32	quantitatively transferred to the prepared G25 column
33	and eluted with PBS/azide. Six drop fractions are

1	coll cted into p lystyren tubes (LP2). The column is
2	eluted until both th protein and the (1251) iodid
3	peaks have been eluted and the radioactivity in all of
4	the fractions is measured.
5	
6	The radioactivity incorporated into the protein can be
7	calculated thus:
8	
9	radicactive counts in protein = original total
10	counts - counts in iodide peaks
11	<del>-</del>
12	The radiolabelled IgG (referred to now as "isotope") is
13	then used in an assay for (pig) antibodies in the
14	neonatal pig, as follows:
15	
16	Materials
17	
18	PBS + 0.01% Azide - Oxoid
19	PBS/BSA 1% - BSA-Sigma
20	Isotope - rabbit anti-pig IgG whole molecule with
21	$12-18 \times 10^3$ counts/min.
22	Heat inactivated sera (56°C 30 mins)
23	Anticoagulated blood samples.
24	
25	<u>Method</u>
26	
27	1. A 1% suspension of rabbit red blood cells in PBS
28	was prepared and 100µl amounts were added to
29	tubes. Cells are spun to a button discarding
30	supernatant.
31	
32	2. Serial dilutions of inactivated sera were prepared
33	in PBS/BSA from adult pig (positive control),

	•
1	neonatal pig (test sample) r rabbit (negative
2	control). 0.025ml amounts were added to red cell
3	buttons in duplicate. Tubes were incubated at 4°C
4	for 4 hours.
5	
6	3. After incubation tubes were washed three times in
7	PBS/BSA 0.05ml of Isotope was then added to each
8	tube and incubated overnight at 4°C.
9	
10	4. Tubes were rewashed three times and 1 min counts
11	were performed on gamma counter.
12	
13	5. Results are plotted as number of counts/min
14	against titre.
15	
16	The results are shown in Figure 2. Rabbit serum was
17	used as a negative control and adult (ie suckled) pig
18	serum as a positive control. It can be seen that the
19	level of pig antibody in the pre-suckled pig 2 is
20	comparable to that of the negative control.
21	
22	EXAMPLE 3
23	
24	Demonstration of Relevance of Complement C3 to
25	Xenograft Destruction
26	
27	Complement deficient guinea pigs derived from the
28	strain described by Burger et al (Eur. J. Immunol 16
29	7-11 (1985)) were grafted with hearts using essentially
30	the same technique as that described for the
31	rabbit-to-pig xenografts in Example 1. Rats were
32	anaesthetised with ether inhalation and hearts cooled

with cardioplegia and excised as previously described.

- Guinea pig donors were anaesthetised with intravenous 1 valium and intramuscular hypnol. Hearts were implanted 2 into the neck as previously described. For control 3 guinea pigs, i.e. those with normal complement levels, 4 graft rejection normally took place within a few 5 minutes, thus making it unnecessary to close the neck. 6 In experimental animals the neck was closed and hearts 7 monitored by twice daily palpation. Normal ECGs were 8 observed for several hours post surgery, indicating no 9
- 11

### 12 EXAMPLE 4

hyperacute rejection.

13

14 A. Pig Lymphocytes and Kidney Cells Activate Human
15 Complement by the Alternative Pathway

16

Following the technique of Grabar and Williams 17 (Biochim. Biophys. Acta 10 193 (1953)), agarose gels 1 18 were poured onto 8 x 8cm glass plates (Figure 3). 19 of gel mixture was required, and this consisted of 5ml 20 2% agarose and 5ml veronal buffer (VB).. (VB is 75mM Na 21 barbitone, 10mm EDTA, 10mm NaN2, pH 8.5.) The agarose 22 and VB were mixed together at 60°C just before use. 23 Gels were poured and cooled on a level platform. When 24 set, the gel consisted of 1% agarose and had a depth of 25 about 1.5mm. 26

27

Wells 3 with a diameter of 3mm were cut about 1cm from one end of the gel. Each well could contain about 8µl of the sample to be run. The sample had no special preparation apart from the addition of enough bromophenol blue to colour it. After application of the sample the gel was carefully placed onto the

platform of th electroph resis tank. Cotton wicks 1 soaked in VB (the running buffer) were then gently 2 pressed along the edge of the gel nearest the wells, 3 and another wick was pressed onto the opposite edge of 4 the agarose. (It is important to ensure that the ends 5 of the wicks dip into the buffer reservoirs.) 6 current of 25-30 mA was then passed through the gel 7 until the albumin (visualised with bound bromophenol) 8 reached the positive (anode) wick. The process takes 9 about two and a half hours to three hours. 10 If two or more gels are to be run simultaneously and in parallel 11 12 then the current applied must be increased accordingly so that two gels required 50 mA and three require 75 13 14 mA, and so forth.

15

When electrophoresis was complete, as indicated by the travel of an albumen marker 9 visualised with bromophenol blue, the gel was removed from the electrophoresis tank.

20

B. 2-Dimensional Crossed Immunoelectrophoresis (2-D
 Rockets)

23

Strips 11 (Figure 4) containing the electrophoresed 24 proteins from (A), were cut and laid at one end of a 25 26 new glass plate 13. A 1:1 mixture 15 of 2% agarose: VB containing about 1% antiserum to the protein to be 27 visualised was then poured onto the plate and allowed 28 29 The antiserum was added to the agarose/VBS mixture when this had cooled to a temperature of about 30 31 50°C.

32

- The rocket plat was then electrophoresed as described 1 2
- above, with the end of the gel c ntaining th
- dimension strips connected via a cotton wick to a
- negative electrode (cathode) 17 and the opposite end 4 5
- connected to an anode 19. The gels were
- electrophoresed overnight at a current dependent on the 6 7
- size of the gels; 10mA is needed for each 8cm length of
- gel so that a gel of 16cm length requires 20 mA of 8
- current, and so forth. 9

- The proteins are separated by the electrophoresis in 11 12
- the first dimension and quantified and visualised by 13
- electrophoresis in the second dimension, staining for 14
- the purpose of visualisation will now be described. 15

C. Squashing and Staining Gels 16

17

- This procedure is the same for either conventional 18 19
- immunoelectrophoresis or rockets. The gel to be 20
- stained was covered with 1 layer of fibre-free POSTLIP 21
- (Trade Mark) paper (Adlard Evans & Co), pre-moistened 22
- with water. This was then covered with 6 layers of 23
- absorbent paper towelling. The assembly was squashed 24
- for 1 hour, after which all the paper was removed and 25
- the r ocess repeated.

26

- **Z**7 After the second squash the gel was dried under a 28
- current of warm air and then soaked in PBs for at least 29
- 1 hour to remove non-precipitated protein. The gel was 30
- then dried again, and stained for 10 minutes in a solution of 0.5% w/v coomasie brilliant blue G250, 45% 31
- H<sub>2</sub>O, 45% methanol, 10% acetic acid. 32

- 1 gel was d -stained by continu us washing in 20% 2
- methanol, 6% acetic acid until th background was 3
- clear. It was then finally dried under warm air. 4

- Figure 5 is a reproduction of the dry gel. Rocket 1 is 5
- a negative control containing  $50\mu l$  normal human serum б 7
- (HRS) plus  $25\mu l$  VBS including 10mm EGTA.
- chelator which removes calcium; calcium is essential EGTA is a 8 9
- for classical pathway complement activation, and so the
- presence of EGTA ensures that complement can only be 10 11
- activated by the alternative pathway.
- (larger) peak is C3, and the right-hand (smaller) peak The left-hand 12 13
- is C3bi, a breakdown product of activated C3.
- control, therefore, the small amount of C3bi indicates 14
- only a minor amount of complement activation. 15

- 17 In Rocket 2, 75% pig erythrocytes (v/v) were added to 18
- the buffer cocktail. There is a slight, but probably 19
- not significant, increase in the C3bi level, thereby
- indicating that pig erythrocytes only marginally, if at 20 21
- all, activate human complement by the alternative 22 pathway.
- The reason for this poor response is not 23 clear.

24

- In Rockets 3 and 4, 75% pig lymphocytes (v/v) or 75% 25 26
- pig kidney cells (v/v), respectively, were added to the 27
- buffer cocktail. In each case there was an appreciable 28
- rise in the C3bi level, indicating activation of human 29
- complement by the pig lymphocytes.

30 31

1 Results

2

- The results are shown in Figure 6. It can be seen that 3 4
- pig lymphocytes are lysed by human serum only in the
- presence of non-pig (ie rabbit or human) complement, 5
- but not in the presence of pig complement. 6
- inference is that one or more homologous complement 7
- restriction factors present on pig cells successfully 8
- down-regulate the action of pig complement but not the 9
- action of human or rabbit complement. 10

11 12

#### EXAMPLE 6

13

32

33

The purpose of this example is to demonstrate that 14 antibody can cause hyperacute rejection. 15 The concept upon which this application is based arose as a result 16 of the observation that hyperacute rejection may take 17 place in the absence of anti-graft antibodies but 18 requires functional complement. 19 Because this is a novel observation there are no experiments in the 20 literature which formally demonstrate that antibody can 21 cause xenograft rejection. 22 Since in the presence of 23 naturally occurring antibody it is difficult to determine whether these antibodies are playing a role 24 or not such an experiment is not easy to perform. 25 this example the role of antibody has been demonstrated 26 by turning a concordant xenograft into a discordant 27 xenograft by infusion of antibody of appropriate 28 specificity. Recipients used in this study were male 29 rats of the PVG strain (RTIC) (Banting & Kingdom, 30 Bicester, Oxon., UK) between 3 and 6 months old 31

SUBSTITUTE SHEET

weighing 250-300 g. Heart donors were Syrian hamsters

also obtained from Banting & Kingdom and weighing

- betw en 100 and 150 g. 1 Heart grafting was performed according t the meth d of Heron (loc. cit. in Example 2
- 1). Hamster hearts were grafted into the neck of the 3
- rats joining the aorta to the carotid artery and the 4
- pulmonary artery to the jugular vein by means of a cuff 5 6
- technique. All other vessels were ligated. 7
- started beating minutes after the release of vascular
- clamps and were monitored by external palpation. 8 9
- operations were carried out on animals anaesthetised by
- inhalation of halothane and oxygen. 10

- Anti-hamster lytic antibody levels were measured as 12 13
- follows: 50  $\mu$ l of 1% hamster erythrocyte solution were 14
- added to 50  $\mu$ l of test serum which had been diluted 15
- serially. 50  $\mu$ l of a 1 in 7 dilution of baby rabbit 16
- complement (Sera Lab, Crawley Down, Sussex) were added and incubated for 1 hour at 37°C. 750  $\mu$ l of complement 17
- fixation diluent were added and centrifuged (Beckman 18
- MICROFUGE, 13000 rpm for 4 minutes) after which the 19
- 20  ${\tt OD}_{415}$  was measured in the supernatant. (The word 21
- MICROFUGE is a trade mark.) Positive and negative 22
- controls were CFD and distilled water added to a 1% 23
- solution of cells respectively. The results of the 24
- $\mathtt{OD}_{415}$  readings were plotted against the serum titration 25
- on the x-axis. As can be seen from Figure 7, grafting 26
- a hamster heart into a rat results in the rat producing 27
- very high titres of lytic anti-hamster antibodies. 28
- Sera from some of these rats were separated into their 29
- component protein fractions by column chromatography on 30
- SEPHADEX G200 (Pharmacia GB Ltd, London) using standard 31
- column chromatography techniques ("The use of SEPHADEX in the separation, purification and characterisation of 32
- biological materials", Curling in Exp. in Physiol. and 33

Biochem, 3 (1970) 417-484 (G.A. Kerkut, Ed.) Academic ı Press, London and New Y rk, 1970). (The word SEPHADEX 2 is a trade mark.) 3 Each of the 7ml fractions collected from the column were assayed for lytic anti-hamster activity as described above. 5 Pigure 8 demonstrates that despite the fact that these antibodies were 6 induced as a result of heart grafting the anti-species 7 activity resides almost exclusively in the IgM 8 fraction. After assaying for activity, fractions were 9 concentrated using CX10 ultrafilters (Pharmacia) to a 10 concentration of 0.5 mg/ml and stored at -70°C until 11 12

13

To test for their ability to destroy a xenograft as 14 opposed to just lysing red cells, hamster hearts were 15 grafted into the necks of naive rats. 16 hamster heart beat was established either 2ml of neat 17 serum or 0.5 mg of purified immunoglobulin containing 18 lytic anti-hamster antibodies were infused intra-19 venously into the rat. 20 Both the unseparated serum and the 0.5 mg of IgM consistently caused the hamster heart 21 graft to be destroyed within 15 minutes. 22 infusion of IgG were inconsistent with some 23 Results from preparations causing the graft to fail while, 24 others, the graft continued to beat. When albumin from 25 the G200 column was infused as a control heart grafts 26 always survived and were rejected in the normal time 27 for this model which is 3 days. This demonstrates that 28 the binding of this antibody to a graft can induce its 29 hyperacute destruction. 30

31

32

#### EXAMPLE 7

1

The data so far presented in this application have 3 demonstrated that the destruction of a xenograft can 4 involve complement activation either by the alternative 5 pathway or by antibody-mediated complement activation 6 (the classical pathway). 7 Furthermore, complement regulators on the surface of the xenograft target can 8 protect it from destruction by homologous but not 9 10 heterologous complement. The critical activation step common to both complement activation pathways is the 11 cleavage of the complement component C3. This cleavage 12 is brought about by the C3 convertage, C4b2a (the 13 classical pathway C3 convertase) or the convertase 14 C3bBb (the alternative pathway C3 convertase). 15 enzymes cleave C3 to C3b which, in turn, can engage the 16 alternative pathway to form more C3 convertages (the 17 feed-back loop). As a result the complement system is 18 rapidly able to amplify the deposition of C3b on a 19 "foreign" target. Much of the C3b however does not 20 successfully interact with the foreign target and 21 22 remains in the fluid phase and can thus indiscriminately bind to the cells of the host. 23 order to protect these cells from attack by the 24 indiscriminate binding of complement, control proteins 25 have evolved to inactivate complement components either 26 in the fluid phase or bound to self tissues. 27 glycoproteins which are involved in controlling C3 are 28 genetically all associated within one region of human 29 chromosome 1 called the RCA (regulators of complement 30 activation) locus. In this example we demonstrate that 31 mouse cells which have acquired through fusion 32 techniques the human chromosome 1 and express proteins 33

- of the RCA locus on their surface behave in an in vitro 1
- assay of xenograft destruction as th ugh they were 2
- human cells and not mouse cells. 3

5 Cell Lines

6

- T5 is an Epstein Barr virus-transformed tonsil B-cell 7
- line produced by the technique of Bird et al. (Nature
- 289 300-301 (1981)). 9 Blo is a human anti-tetanus
- monoclonal antibody producing hybridoma which was 10 11
- derived from the fusion of a human B lymphoblastoid
- line (BLL) with the mouse myeloma cell line X63-AG8.653 12 13
- (Kierney et al. (J. Immunol. 123 1548-1550 (1979)). 14
- and B10 cell lines are obtainable from Ms C Carter and 15
- Dr N C Hughes-Jones of the MRC MITI Group at Babraham, 16
- DB3 is a mouse hybridoma cell line which 17
- produces anti-progesterone monoclonal antibody (Wright 18
- et al. Nature 295 415-417 (1982)). The following 19
- oligonucleotide primers specific for human chromosome 1 20 were procured:
- (5'-CCACAGGTGTAACATTGTGT-3') [SEQ ID 21
- No: 1] and (5'-GAGATAGTGTGATCTGAGGC-3') [SEQ ID NO: 2]; 22
- these are, respectively, upstream and downstream 23
- primers of human antithrombin 2 (AT3) gene known to be on human chromosome 1 (Wu et al. Nucl. Acids Res. 17 24
- 6433 (1989)). The oligonucleotides can be synthesised 25
- 26 by techniques well known to those skilled in the art.

- High molecular weight genomic DNA was prepared using 28
- the method of Herrmann and Frischauf (Methods Enzymol. 29
- 152 180-183 (1987)). In brief, 100x10<sup>6</sup> cells from each 30
- cultured cell line were lysed by 5ml of TNE (100mm Tris 31 3 Z
- pH 7.5, 100mM NaCl, 10mM EDTA 1% Sarkosyl) and treated
- with fresh proteinase K (100 micrograms per ml). 33

preparation was extracted with phenol (water saturated ı and equilibrated against 0.1M Tris, pH 8) phenol 2 chloroform (1:1, V/V) and then chloroform isoamyl 3 alcohol (24:1 V/V). 4 precipitation and dialysed against TE (10mm Tris pH8.0, DNA was obtained by ethanol 5 1mm EDTA) made to 100mm in NaCl and TE alone at 4°C. 6 Isolated DNA was analysed on 0.5% agarose gel and the 7 concentration determined by optical density at 260 nm. 8 The polymerase chain reaction (PCR) for each cell line 9 was performed as described by Saiki et al. (Science 239 10 11 487-491 (1988)). In a volume of 100  $\mu$ l containing 500 ng of genomic DNA 1.2 ng of each primer and 2.5 12 units of Tag DNA polymerase (Thermos acquaticus type 3) 13 (Cambio Ltd, Cambridge, UK) using the buffer supplied 14 with the enzyme. The nuclectides (dNTPs) (Boehringer 15 Mannheim Diagnostics and Biochemicals Ltd, Lewis, East 16 Sussex, UK) were at a concentration of 2mM each. 17 was amplfied for 30 cycles using a programmable thermal 18 controller (Genetic Research Instrumentation Ltd, 19 Dunmow, Essex, UK): denaturing 93°C 1 minute: annealing 20 55°C 1 minute: and extension 72°C 2 minutes. 21 the reaction product were analysed directly on a 2% 22 agarose gel run in Tris boric acid EDTA buffer. 23 product size was determined by comparison with <u>Hin</u>cII 24 digested phage X-174-rf DNA (Pharmacia LKB 25 Biotechnology, Upsala, Sweden). 26 27 28 Cultured T5, B10 and DB3 cells were treated with anti-DAF (decay accelerating factor) monoclonal 29 antibody ( Kinoshita et al ((J. Exp. Med. 162 75-92 30 1985)) and fluoroscein-conjugated second antibody. 31 Cells (1x106) were reacted with mouse anti-DAF 32 monoclonal antibody lAlo (IgG2a 10  $\mu$ g/ml in 100  $\mu$ l of 33

- 10% FCS 0.1% azide). 1 1A10 (Kinoshita et al. <u>Immunol.</u> 136 3390-3395 (1986))) was obtained from Dr M 2 Davitz of New York University Medical Centre, New York 3 4 Blank controls were buffer alone. incubation for 2 hours on ice the cells were washed 3 5 times, re-suspended and incubated in 100  $\mu l$  buffer 6 containing 1 in 100 FITC-conjugated goat F(ab')2 7 anti-mouse IG (heavy and light chains affinity purified 8 9 and human IG absorbed) (Tago Immunochemicals Inc, Burlingame, California, USA) for one hour on ica. 10 cells were incubated only with the second antibody as 11 staining controls. 12 Since DB3 is a mouse IgG1-secreting cell line, FITC-conjugated sheep anti-mouse IgG2A (1 in L3 40, The Binding Site Ltd, Birmingham, UK) or the goat 14 anti-mouse IG preabsorbed with equal volumes of DB3 15 cells were also used in order to eliminate anti-IgG1 16 17 reactivity occurring when staining DB3 cells. cells were extensively washed and resuspended in 200  $\mu$ 1 18 19 DAF positive cells were detected using a Beckton Dickinson FACS-STAR apparatus for 20 fluorescence-activated cell sorting (FACS) analysis. 21 (The expression FACS-STAR is a trade mark.) 22 23
- The PCR method was used to determine the presence of 24 human chromosome 1 in three different cultured cell 25 26 T5 (human), B10 (human-mouse) and DB3 (mouse-mouse). Figure 9 shows that after amplification 27 both T5 and B10 had a band size of 495 base pairs 28 29 whereas DB3 (ie the mouse-mouse hybrid) had no band at 30 It has been reported that PCR products using AT3 primers consisted of 2 alleles, sized 572 base pairs 31 (allele 1) and 496 base pairs (allele 2) (Wu at al., 32 loc. cit.). The bands found in T5 and B10 genomic DNAs 33

- 1 correspond to all 1 2. This demonstrates that the 2 human m use hybrid cell line BlO c ntain d human
- 3 chromosome 1.

- FACS analysis for the presence of DAF showed that the majority of the human T5 cells (85.7%) stained positive with anti-DAF monoclonal antibody. A similar level (83.1%) of positive cells was found in the name (burney)
- 8 (83.1%) of positive cells was found in the mouse/human
  9 hybrid Blo cells. The mouse-mouse hybrid Blo cells.
- 9 hybrid B10 cells. The mouse-mouse hyrbid DB3 cells
  10 showed identical staining nattorns for both and
- showed identical staining patterns for both anti-DAP
- 11 treated and untreated preparations. However, this
- 12 anti-mouse IgG1 reactivity was removed if (1)
- 13 FITC-conjugated sheep anti-mouse IgG2a was used or (2)
- 14 the above goat anti-mouse IgG was preabsorbed with DB3
- 15 cells. The results indicate that human-mouse hybrid
- 16 cell line B10 express human DAF on the cell membrane
- 17 surface as detected by specific anti-DAF monoclonal
- 18 antibodies. The level of expression is the same as for
- 19 the human cell line T5. A mouse-mouse hybridoma cell
- 20 line does not express human DAF.

21

- 22 Chromium release cytotoxic cell killing studies were 23 performed on these cell lines as is described in
- 24 Example 5 above. Figure 10 shows that, when pig
- 25 anti-human antibodies are incubated with the T5 human 26 cell line the addition of makin antibodies
- 26 cell line the addition of rabbit complement caused 27 lysis whereas no lysis compress the beauty and the complement caused
- 27 lysis whereas no lysis occurs when human complement is 28 added because, of course, the T5 cell line will possess
- 29 human HCRFs. This is confirmation of the results of
- 30 Example 5. When human antibodies are used on the human
- 31 cell line no lysis occurs either with human complement
- 32 or with rabbit complement, showing there are no
- 33 auto-antibodies. The chromium release technique does

not allow for incubations to be continued long enough ı to detect any signficiant lev ls of alternative pathway 2 activation of th rabbit complement by the human cells 4 (Figure 11). However, when human antibodies are incubated with the DB3 mouse-mouse hybridoma cell line 5 (Figure 12), cell killing is achieved by both rabbit 6 complement and human complement demonstrating that 7 indeed human complement can function in such an assay. . 8 When the B10 human-mouse hybrid, possessing human 9 chromosome 1 and known to be expressing at least DAF, 10 was used then rabbit complement caused lysis of the 11 cell line whereas human complement fails to cause lysis 12 of the cell line (Figure 13). The explanation for this 13 is that the human HCRPs being expressed by virtue of 14 possession of chromosome 1 on the mouse-human hybrid 15 have inhibited the activity of the human complement. 16

17

18 EXAMPLE 8

19

The preceding example demonstrates that possession of 20 chromosome 1 can prevent xanograft cell destruction. 21 While this is strong circumstantial evidence that it is 22 the CRA locus which is protecting the mouse cell from 23 xenograft destruction this example provides formal 24 25 In this example, the effect of transfecting non-human cell lines with human MCP and exposing them 26 to human or rabbit complement is demonstrated. 27

- cDNAs were produced for MCP as described in detail by 29 Lublin et al. (J. Exp. Med. 168 181-194 (1988)). 30
- Construction of transfected cell lines was performed 31 using the expression plasmid SFFV.neo using the 32
- technique described by Fuhlbrigge et al. (Proc. Natl. 33

- Acad. Sci. 85 5649-5653 (1988)). This contains the Friend spleen focus forming virus 5' long terminal 2 repeat (SFFV.LTR) (Clark and Mak (Nucl. Acids Res. 10 3315-3330 (1982)) and (Proc. Natl. Acad. Sci. 80 4 5037-5041 (1983))). 5 Cell lines were obtained from the American Type Culture Collection 12301 Parklawn Drive, 6 7 Rockville, Maryland, USA. Cell lines used were CHO-Kl (ATCC CCL 61) and NIH/3T3 (ATCC CRL 1658). Expression 8 9 of the gene was confirmed using a monoclonal antibody to MCP (Andrews et al. Ann. Hum. Genet. 49 31-39 10 (1985)) and FACS analysis as already described. 11 some cases cell lines were selected for high level 12 expression of MCP by cell sorting on the FACS using 13 14 standard techniques. 15 This example illustrates the effect of transfecting CHO
- 16 17 cells with MCP. Because these cell lines grow as monolayers, cell killing was assessed by the terminal 18 adenine uptake assay as descibred by de Bono et al. 19 (Immunology 32 221-226 (1977)). In brief, this assay 20 involved incubation of cell cultures in flat-bottomed 21 sterile 96 well plates with complement and antibody. At 22 the end of the experimental incubation period, cell 23 24 viability is assessed by the ability of the culture to take up radioactive adenine. Viable cells will take up 25 the adenine, dead cells will not; thus viable cells 26 have high counts, dead cells have low counts. 27

In common with many transformed cells, CHO is insensitive to naturally occurring antibodies and the action of the alternative pathway of complement. However, these cells are sensitive to those antibodies which as has been demonstrated cause hamster heart

- xenograft destructi n as described in Example 6. Sin e 1 CHO c lls ar d rived from hamster, thes 2 antibodies killed the CHO cells with both human and rabbit 3 complement (Figure 14). When CHO cells are transfected 4 with human MCP, the cells can only be lysed in the 5 presence of rabbit complement. 6 Human complement has 7
- been inhibited by the presence of the human MCP on the 8
- surface of the hamster cell line (Figure 15). Evidence 9
- that the failure of the cells to be killed is indeed 10
- due to a failure of C3 convertase is provided by analysis of the breakdown of the human C3 after 11
- 12 incubation of the CHO cells by
- rocket immuno-electrophoresis as descibred in Example 4 above. 13
- As can be seen, no breakdown occurs above complement 14 15
- only control levels (Figure 16). 16

These data confirm that genetically engineering 17 18

- complement down-regulatory proteins on the surface of 19
- non-human cells will protect those cells from the 20
- mechanisms of hyperacute xenograft destruction which 21
- have, as a common feature, a requirement for the 22
- cleavage of the C3 component of complement. 23

24 EXAMPLE 9

- Pollowing the procedure of Example 8, 26 3T3 mouse 27
- fibroblast cells were transfected with cDNA coding for
- MCP (MCP clone K5.23). 28 <sup>51</sup>Cr was added to the cells as 29
- described in Example 5. One volume of cells was then incubated with one volume of human heat-inactivated 30
- complement and one volume of human complement 31
- pre-absorbed at 4°C with mouse spleen calls to remove 32
- anti-mouse antibody from the human complement. 33

- 1 mixture and serial dilutions with complement were 2 plat d out. General conditions and features of the
- 3 chromium release assay are as described in Example 5.
- 4 The results for clone K5.23 are shown in Figure 17,
- 5 which also shows, as a control, the effect of the MCP
- 6 cDNA being introduced in the reverse orientation (in
- 7 which case it is not transcribed). Correctly
- 8 transcribed MCP cDNA confers protection on the cells
- 9 from killing, as evidenced by the relatively low level
- 10 of 51Cr release, whereas non-transcribed cDNA does not
- 11 confer significant protection, as evidenced by the
- 12 relatively high level of <sup>51</sup>Cr release.

#### 14 EXAMPLE 10

15

- 16 Similar results to those described in Example 8 above
- 17 can be obtained with L1/210 cells (a mouse leukaemic
- 18 cell line) transfected with with the cDNA for DAF.
- 19 cDNAs were produced for DAF as described in Lublin &
- 20 Atkinson (Ann. Rev. Immunol, 7 35-58 (1989)).

ZĮ

#### 22 EXAMPLE 11

23

- 24 cDNA for MCP was prepared and ligated into SFFV.neo, as
- 25 in Example 8 above.

- 27 Using this DNA preparation transgenic mice were
- 28 produced as described in Manipulating the Mouse Embryo,
- 29 A Laboratory Manual by B. Hogan et al, Cold Spring
- 30 Harbour Laboratory (1986). Ten to fifteen (CBAxB10)f1
- 31 female mice, 3-4 weeks old, were induced to
- 32 superovulate by intraperitonal injection of 5 units
- 33 serum gonadotrophin from pregnant mares (supplied

- commercially as Folligon) f ll wed 48 hours lat r by I 2 3
- intraperitonal injection of 5 units chorionic
- gonadotrophin from human pregnancy urine (supplied 4
- commercially as Chorulon). 5
- The females were put to on the day of the Chorulon injection, with 6
- (CBAxB10)F1 males and the next day females with vaginal 7
- plugs were killed by cervical dislocation and 8
- fertilized ova were isolated from their oviducts. 9 10
- Three to four hundred ova, 11
- contained two pronuclei clearly visible under Nomarski 12
- differential interference contrast optics at 400 x magnification.
- 13 One of the two pronuclei was injected 14
- with approximately 2000 copies of the DNA preparation 15
- containing the MCP cDNA transgene in concentrations 16
- ranging from 0.5 to 2  $ng/\mu$ l. 17
- Ova that survived the microinjection were reimplanted 18 19
- into the oviducts of (CBAxB10)F1 females that had mated 20
- the previous night with vasectomized males and were
- therefore pseudopregnant (ie, they had ovulated and 21 22
- their hormonal state was that of pregnancy but their 23
- own occytas had not been fertilized). Approximately 30 24
- microinjected ova were transferred to the oviducts of 25
- each pseudopregnant female, under anaesthesia, either
- on the same day of microinjection or the next day when 26 27
- the ova were at the 2-call stage.
- 28
- ensued and seventeen mice were born from ten mothers. Normal gestation 29
- Screening of the offspring was done by slot blot and/or 30 31
- Southern blot (see Example 8), and also PCR, analysis
- of DNA from tail skin cells, utilizing 32P-labelled 32
- probes and primers that recognize the transgene. 33

of th offspring, a male, proved to be transgenic for the MCP DNA sequence.

3

#### 4 EXAMPLE 12

5

- The procedure of Example 11 was repeated, except that
- 7 the cDNA for DAF, as described in Example 10, was used
- 8 in place of the cDNA for MCP. Twenty three offspring
- 9 were born from ten mothers. Three of them (two female,
- 10 one male), transgenic for DAF, were obtained, as shown
- 11 by Southern blotting.

12

#### 14 EXAMPLE 13

15

- 16 The male mouse obtained in Example 11, containing a
- 17 human MCP cDNA transgene was allowed to grow to
- maturity and mated with a (CBAxB10)F1 female. Eleven
  offspring resulted mail and pro-
- offspring resulted. Tail cell DNA from each offspring
- 20 was screened by slot-blot analysis, using labelled
- 21 human MCP cDNA as a probe, to determine whether the
- transgene had been inherited. The results are shown in the upper part of Figure 18. It can be seen that
- 24 offspring 0, 1, 5, 7, 8 and 10 have inherited. (Four
- 25 controls were undertaken: human DNA (H); mouse DNA
- 26 (M); mouse DNA mixed with 10 pg human MCP labelled
- 27 CDNA; and mouse DNA mixed with 100 pg human MCP
- 28 labelled cDNA.)

29 30

#### EXAMPLE 14

- 32 The male mouse obtained in Example 12, containing a
- 33 human DAF cDNA transgene was allowed to grow to

1	maturity and mated with a (CBAxB10)F1 female. For each
2	of the resulting offspring, tail cell DNA was screened
3	by slot-blot analysis, using labelled human DAF cDNA as
4	a probe, to determine whether the transgene had been
5	inherited. The results are shown in the lower part of
6	Figure 18. It can be seen that offspring 13.3 (a
7	female) has inherited. (Four controls were undertaken:
8	human DNA (H); mouse DNA (M); mouse DNA mixed with 10
9	pg human DAF labelled cDNA; and mouse DNA mixed with
10	100 pg human DAF labelled CDNA.)

1 CLAIMS

2

- A method of transplanting animal tissue into a 1.
- recipient, wherein the tissue is derived from a donor 4
- of a different species from the recipient, the donor 5
- 6 species being a discordant species with respect to the
- recipient, the method comprising grafting the tissue 7
- into the recipient and providing in association with
- the grafted tissue one or more homologous complement 9
- restriction factors (HCRFs) active in the recipient 10
- species to prevent the complete activation of 11
- 12 complement.

13

- 14 A method as claimed in claim 1, wherein the tissue 2.
- 15 is an organ.

16

- A method as claimed in claim 2, wherein the organ 17
- is a heart, lung, liver, kidney, pancreas or thyroid. 18

19

- 20 A method as claimed in claim 1, wherein the tissue
- comprises blood or haematopoietic cells, Islets of 21
- 22 Langerhans, brain cells or cells from endocrine 23
- organs.

24

- A method as claimed in any one of claims 1 to 4, 25
- wherein the HCRF interferes with that part of the 26
- complement activation cascade which is common to both 27
- the classical and alternative pathways. 28

29

- A method as claimed in any one of claims 1 to 5, 30
- wherein the HCRF is a natural HCRF. 31

. 1	/. A meth d as claimed in claim 5, wherein the HCRF
2	
3	
4	8. A method as claimed in claim 7, wherein the HCRF
5	is or has the activity of:
6	
7	Factor I (also previously known as C3b inactivator
8	or KAF);
9	
10	Factor H;
11	
12	C4 binding protein;
13	
14	DAF (also known as CD55);
15	
16	Membrane Cofactor Protein (MCP; also known as CD46
17	and first described as gp45-70 and further known
18	as gp66/56);
19	
20	CR1 (also known as C3b/C4b receptor or CD35);
21	and/or
22	
23	CR2 (also known as CD21, C3.dg receptor, 3d/EBV
24	receptor and p140).
25	
26	9. A method as claimed in any one of claims 1 to 8,
27	wherein the HCRF has the activity of a natural HCRF
28	whose gene is located in the RCA (regulator of
29	complement activation) locus, which maps to band q32 of
30	chromosome 1.
31	
32	10. A method as claimed in claim 5, wherein the HCRF
33	regulates complement activation at C8 and/or C9.

- 1 11. A method as claimed in claim 10, wherein the HCRF is or has the activity of:

  C8bp (also known as HRF or MIP);

  P-18 (also known as HRF-20, CD59 or MIRL); or

  SP40.40.
- 10 12. A method as claimed in any one of claims 1 to 11, 12
- 13 13. A method as claimed in any one of claims 1 to 12, 14 wherein the HCRF is provided in such a way that it is 15 integrated with the cell membrane on donor tissue.
- 17 14. A method as claimed in claim 13, wherein the donor tissue is transgenic in that it contains and expresses nucleic acid coding for one or more HCRFs active in the recipient species when grafted into the recipient.
- 23 15. A method as claimed in any one of claims 1 to 14, 24 wherein the recipient species is human.
- 26 16. A method as claimed in any one of claims 1 to 15, wherein the donor species is a pig.
- 29 17. Graftable animal cells or tissue of a donor species, the cells or tissue being associated with one or more homologous complement restriction factors active in the intended recipient species to prevent the complete activation of complement, the donor species

b ing a discordant species with resp ct to the 3

- 4 A transgenic animal having transplantable tissue,
- which does not give rise to kenograft rejection on 5 6
- transplantation into or exposure to the immuno system
- of at least one discordant species. 7 8
- 9 The use of animal tissue derived from a donor 10
- species and one or more homologous complement 11 12
- restriction factors active in a recipient species, 13
- wherein the donor species is a discordant species in
- relation to the recipient species, in the preparation 14
- of tissue graftable into the recipient species. 15
- 20. A transgenic animal having cells capable of 16 17 18
- expressing a homologous complement restriction factor of another species.

19

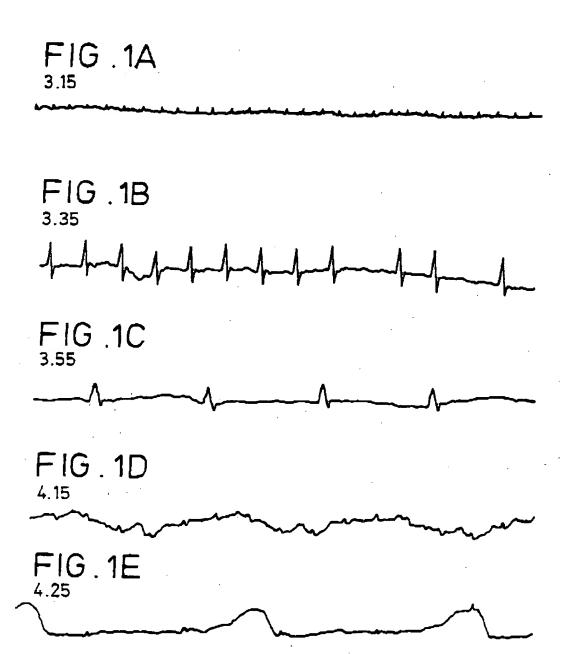

- 21. A non-transformed animal cell capable of 20 21
- expressing one or more homologous complement 22
- restriction factors active in a species which is 23
- discordant with respect to the animal cell. 24
- 22. Recombinant DNA comprising DNA coding for at least 25
- one homologous complement restriction factor and one or 26
- more sequences to enable the coding DNA to be expressed **27** 28
- by a non-transformed animal cell. 29

- 30 DNA as claimed in claim 22, wherein the animal 31
- cell is a cell of a transgenic animal genetically
- incorporating the construct. 32

a £

	<b>3</b> /
1,2	cultured organ or other tissue such as
3	Langerhans.
4	
5	25. A genetic construct suitable for incorporation
. 6	- de gametic material of an animal 4-
7	animal, the construct comprising me
8 9	teast one nomologous complement
10	and one or more sequences to enable the
11	be expressed in at least some was
12	transgenic animal genetically incorporating the construct.
13	
14	26. A genetic construct as claimed in claim 25, which
15	is in the form of a YAC.
16	
17	27. A method of preparing a transgenic animal, the
18	
19 20	
21	Toucht Lactor and one on
22	the couling DNA to be evereded in the
23	some cells of the transgenic animal.

VA OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND U	NSEARCHABLE 1
This international agench report has not been established in respect of certain	claims under Article 17(2) (a) for the following reasons:
1. Claim numbers 1 = 1 fibecause they relate to subject matter not requir	
Pls. see Rule 39.1 (iv) - PCT ;	
Method for treatment of the human or therapy as well as disconnected	or animal body by surgery
or therapy as well as diagnostic met	thods.
2. Claim numbers, because they relate to parts of the international	
ments to such an extent that no meaningful international search can be	carried our, specifically:
·	
,	•
	•
Claim numbers because they are dependent claims and are not di	refield in accordance with the second and third semismoss of
PCT Rule 6.4(a).	•
VL DESERVATIONS WHERE UNITY OF INVENTION IS LACKIN	1G 7
This international Searching Authority found multiple inventions in this interna-	witeus selication se tollows:
·	
•	
1. As all required additional search fees were timely paid by the applicant, t	his international search report covers all searchable claims
of the international application.	
2. As only some of the required additional search fees were timely paid by those claims of the international application for which fees were paid, a	
where or the majorisaminal apparation for which test were paid, a	pecurcul Cantel
L. No required additional search (see were timely paid by the applicant, Co	mesquently, this international search report to restricted to
the invention first mentioned in the claims; it is covered by claim number	HTS:
4 A and acceptable to the second seco	
4. As all searchable claims could be searched without effort justifying an a invite payment of any additional res.	additional fee, the international Searching Authority did not
Remark on Proteit	
The Edditional equich fees were accompanied by applicant's protest.

## ANNEX TO THE INTERNATIONAL SEARCH REPORT ON INTERNATIONAL PATENT APPLICATION NO.

GB 9001575 SA 40976

This among lists the patent family members relating to the patent documents cited in the above-mentioned international asserts report. The members are as consciped in the European Patent Office EDP file on 05/02/91.

The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
